

•An

oil explorer performs a seismic test to determine whether oil is likely to be found in a certain area. The probability that the test indicates the presence of oil is 90% if oil is indeed present in the test area and the probability of a false positive is 15% if no oil is present in the test area. Before the test is done, the explorer believes that the probability of presence of oil in the test area is 40%. Use Bayes' rule to revise the value of the probability of oil being present in the test area given that the test gives a positive signal.

$$P(\text{have oil} \mid \text{positive}) = P(\text{have oil} \cap \text{positive}) / P(\text{positive})$$

$$P(\text{positive} \mid \text{have oil}) = P(\text{have oil} \cap \text{positive}) / P(\text{have oil})$$

$$0.9 = P(\text{have oil} \cap \text{positive}) / 0.4$$

$$0.36 = P(\text{have oil} \cap \text{positive})$$

$$P(\text{have oil} \mid \text{positive}) = 0.36 / P(\text{positive})$$

$$P(\text{positive}) = P(\text{positive} \cap \text{have oil}) + P(\text{positive} \cap \text{no oil})$$

$$P(\text{positive}) = P(\text{positive} \mid \text{have oil})P(\text{oil}) + P(\text{positive} \mid \text{no oil})P(\text{no oil})$$

$$P(\text{positive}) = (0.9)(0.4) + (0.15)(0.6)$$

$$P(\text{positive}) = 0.45$$

$$P(\text{have oil} \mid \text{positive}) = 0.36 / 0.45$$

$$P(\text{have oil} \mid \text{positive}) = 0.8$$
